A Multiresolution Scheme for More Efficient Simulation on Adaptive Mesh Refinement Blocks?

└─Introduction

Introduction

The following project is concerned with the numerical solution of systems of conservation laws of the form

$$\mathbf{U}_t + \mathbf{F}(\mathbf{U})_x = 0$$

where $\mathbf{U} = (\rho, \rho u, E)$ is a vector of conserved quantities and $\mathbf{F}(\mathbf{U})$ is a flux vector. Consider a standard finite-volume discretization, with midpoint rule

$$\frac{\partial \mathbf{U}_i}{\partial t} = -\frac{1}{h} \left(\mathbf{F}_{i+\frac{1}{2}} - \mathbf{F}_{i-\frac{1}{2}} \right)$$

where the i denotes spatial index.

Introduction

Adaptivity

The interest is in solution-adaptive methods:

A Multiresolution Scheme for More Efficient Simulation on Adaptive Mesh Refinement Blocks?

└─ Introduction

Adaptivity

The interest is in solution-adaptive methods:

▶ adaptive mesh refinement (AMR) based on local truncation error (or some other estimator)

A Multiresolution Scheme for More Efficient Simulation on Adaptive Mesh Refinement Blocks?

└─ Introduction

Adaptivity

The interest is in solution-adaptive methods:

- adaptive mesh refinement (AMR) based on local truncation error (or some other estimator)
- computations typically done on blocks / patches for efficiency

A Multiresolution Scheme for More Efficient Simulation on Adaptive Mesh Refinement Blocks?

└─ Introduction

Adaptivity

The interest is in solution-adaptive methods:

- adaptive mesh refinement (AMR) based on local truncation error (or some other estimator)
- computations typically done on blocks / patches for efficiency
- inherent "overresolution" in some regions of the mesh by using blocks

└─Introduction

Adaptivity

The interest is in solution-adaptive methods:

- ▶ adaptive mesh refinement (AMR) based on local truncation error (or some other estimator)
- ▶ computations typically done on blocks / patches for efficiency
- ▶ inherent "overresolution" in some regions of the mesh by using blocks
- ▶ can this be addressed by reducing block size? computational tradeoff?

Filling

The filling factor is the number of cells in a block which were flagged, divided by the total.

└─ Multiresolution

a la Harten

- ▶ Besides the AMR concepts, a multiresolution approach was also introduced by Harten. Grid is *not* refined in space. Instead, a wavelet transform is performed on the uniform grid, and the fluxes are interpolated in smooth regions.

- Besides the AMR concepts, a multiresolution approach was also introduced by Harten. Grid is *not* refined in space. Instead, a wavelet transform is performed on the uniform grid, and the fluxes are interpolated in smooth regions.

- "The goal of a multi-scale decomposition of a discrete set of data is a "rearrangement" of its information content in such a way that the new discrete representation, exactly equivalent to the old one, is more "manageable" in some respects." - Arandiga, Donat

Multiresolution

Define multiple, nested grids

$$\mathbf{G}^l = \left\{ x^l_{i+\frac{1}{2}} \right\}^{N_l}_{i=0} = \left\{ x^{l+1}_{i+\frac{1}{2}} \right\}^{N^{l+1}}_{i=0, \text{i even}}.$$

Coarsening of avarage data in cell done via

$$\mathbf{U}^l_i = \frac{1}{2} \left(\mathbf{U}^{l+1}_{2i} + \mathbf{U}^{l+1}_{2i+1} \right)$$

A Multiresolution Scheme for More Efficient Simulation on Adaptive Mesh Refinement Blocks?

└─ Multiresolution

Decomposition

The prediction from coarse to fine is done by

$$\hat{\mathbf{U}}^{l+1}_{2i+1} = \sum_{j=1-s}^{s-1} \gamma_j \mathbf{U}^l_{i+j}$$

The regularity information is assessed by computing detail coefficients as

$$\mathbf{d}^l_i = \mathbf{U}^{l+1}_{2i+1} - \hat{\mathbf{U}}^{l+1}_{2i+1}.$$

A mask $\{\mathbf{m}\}^{N^l}_i$ is created for significant cells.
